I2CXL-MaxSonar[®]- WR/WRC[™] Series High Performance Sonar Range Finder MB7040, MB7047

The I2CXL-MaxSonar-WR series is the first MaxSonar ultrasonic sensor to feature the I2C interface. The sensors have high acoustic power output along with real-time auto calibration for changing conditions (voltage and acoustic or electrical noise) that ensure users receive the most reliable (in air) ranging data for every reading taken. The I2CXL-MaxSonar-WR low power 3V - 5.5V operation provides very short to long-range detection and ranging, in a tiny and compact form factor. The I2CXL-MaxSonar-WR will typically detect objects from 0-cm to 765-cm (3-cm to 625-cm for the WRC) and provide sonar range information from 20-cm out to 765-cm with 1-cm resolution. Objects from 0-cm (3-cm for the WRC) to 20-cm typically range as 20-cm.

Features

- I2C bus communication allows rapid control of multiple sensors with only two wires
- High acoustic power output
- Real-time auto calibration and noise rejection for every ranging cycle
- Calibrated beam patterns
- Continuously variable gain
- Object detection up to the front face of the sensor (3-cm for the WRC)
- 3V to 5.5V supply with very low average current draw
- Readings can occur up to every 25mS (40Hz rate)³ for up-close objects. 15Hz rate for full range.
- Triggered operation provides a new range reading as desired
- Ultrasonic signal frequency of 42KHz
- Status pin available to determine sensor state
- Power-up address reset pin available
- Physical dimensions match other XL-MaxSonar-WR/WRC products
- -40° C to $+65^{\circ}$ C operation

Low Power Requirement

- Wide, low supply voltage requirements eases battery powered design
- Low current draw reduces current drain for battery operation
- Fast first reading after power-up eases battery requirements

Benefits

- Acoustic and electrical noise resistance
- Reliable and stable range data
- Sensor dead zone virtually gone
- Low cost
- Quality controlled beam characteristics
- Very low power ranger, excellent for multiple sensor or battery based systems
- Ranging is triggered externally
- Fast measurement cycle
- No power up calibration required
- Perfect for when objects may be directly in front of the sensor during power up
- Easy mounting

² By design

Notes:

³Recommended time between readings of 100ms (10Hz Rate)

performance in their application

¹Users are encouraged to evaluate the sensors

About Ultrasonic Sensors

Our ultrasonic sensors are in air, non-contact object detection and ranging sensors that detect objects within an area. These sensors are not affected by the color or other visual characteristics of the detected object. Ultrasonic sensors use high frequency sound to detect and localize objects in a variety of environments. Ultrasonic sensors measure the time of flight for sound that has been transmitted to and reflected back from nearby objects. Based upon the time of flight, the sensor determines the range to a target.

Applications and Uses

- Multi-sensor arrays
- Proximity zone detection
- People detection
- Robot ranging sensor
- Autonomous navigation
- Educational and hobby robotics
- Environments with acoustic and electrical noise
- Distance measuring
- Long range object detection
- Security systems
- Motion detection
- Collision avoidance
- Bin level measurement
- This product is not recommended as a device for personal safety

I2CXL-MaxSonar[®]-WR[™] Circuit

The sensor functions using a variety active components which create an excellent ultrasonic sensor solution. The schematic is shown to provide the user with detailed connection information.

I2CXL-MaxSonar[®]-WR[™] Pin Out

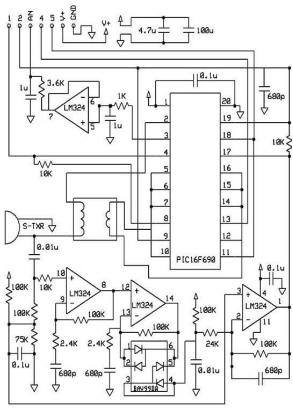

Pin 1- Add-Reset: This pin is internally pulled high by the sensor. On power up, the state of this pin is checked; if left high or disconnected, the sensor will use the address stored in EEPROM for I2C communications. If pulled low (to ground), the sensor will use its

default shipped address for I2C communications for the current power cycle only (to permanently change the address, one must use the I2C Change Address command).

Pin 2- Status- This pin provides a status indicator for the current state of the sensor.

On power up, it will provide a pulse width representation of the address that will be loaded from EEPROM and used, with a length of 100 microseconds \times the 8-bit read/write version of address (~22.4 milliseconds for the default address).

During real-time operation, the line will be driven low while I2C bus communications are active and the sensor is listening for a command. This pin will transition within 50 microseconds of receiving a ranging command to high, and will remain high until after the sensor is ready

to communicate via I2C again after a range cycle. This is provided so users may poll the line to determine if the sensor has finished its ranging cycle, or set up an interrupt to be generated when the sensor is ready to report the latest range reading.

Pin 3-Not Used- This pin is not used for the I2CXL-MaxSonar-WR series.

Pin 4-SDA (I2C Data)— This is the data line for I2C communications. The I2CXL-MaxSonar-WR series operate as I2C slave devices, supporting 7-bit addressing, with a default shipped address of hexadecimal 70 (decimal 112). This corresponds to an equivalent 8-bit address of E0 (decimal 224).

Pin 5-SCL (I2C Clock)- This is the clock line for I2C communications. The I2CXL-MaxSonar-WR series supports I2C clock frequencies up to 100kHz. Clock stretching must be supported by the master device for read requests with a clock speed above 25kHz.

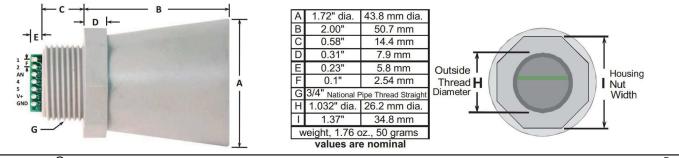

V+- Vcc – Operates on 3V - 5.5V. The average current draw for 3.3V operation is 2.7mA (50mA peak) and for 5V operation is 4.4mA (100mA peak) respectively. Peak current is used during sonar pulse transmit.

GND- Return for the DC power supply. GND (& V+) must be ripple and noise free for best operation.

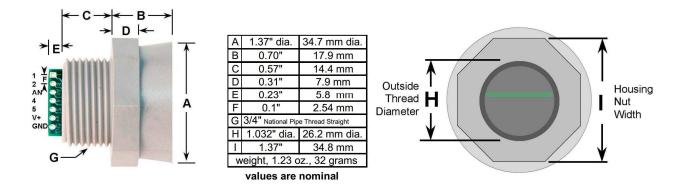

Sensor Minimum Distance - No Sensor Dead Zone

The sensor minimum reported distance is 20-cm. However, the I2CXL-MaxSonar-WR will range and report targets to the front sensor face. Large targets closer than 20-cm will typically range as 20-cm. For the I2CXL-MaxSonar-WRC, objects between 3-cm and 20-cm will typically range as 20-cm.

Mechanical Dimensions I2CXL-MaxSonar-WR

Mechanical Dimensions I2CXL-MaxSonar-WRC

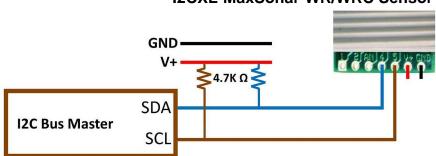

Single Sensor Reference Wiring Diagram

The I2C bus is a bi-directional, two wire interface that consists of a clock line and a data line.

The clock line and the data line both require a pull-up resistor attached to positive supply voltage. The recommended resistance is 4.7 k Ω ; however, the value used is dependent upon the user configuration, with more sensors possibly requiring a lower resistance and users that use only one to two sensors per bus could use a larger resistance for the pull-ups. The I2CXL-MaxSonar-WR series is capable of sinking more current through the pull-up resistors than the I2C specification allows (15mA versus 3mA), so that users may use a lower resistance if it is required for their application. Only one pull-up resistor is required each for the SCL and SDA lines per bus– not per sensor.

The pull-up voltage applied to the I2C clock line and data line should not be more than approximately 0.7 volts above what is applied to V+.

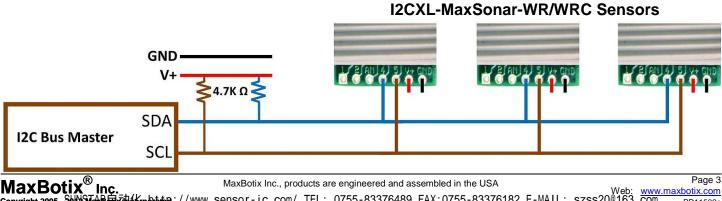

The four minimum required connections to the sensor to obtain basic functionality are: ground and power to GND and V+ respectively, SCL to Pin 5, and SDA to Pin 4.

I2CXL-MaxSonar-WR/WRC Sensor

Multiple Sensor Reference Wiring Diagram

Adding additional sensors to the I2C bus is extremely simple, as long as each sensor is programmed first to a different address (see I2C Address Change for more details), and the bus capacitance is low enough for the pull-up resistors to work properly. GND, V+, SCL and SDA simply need to be connected to the existing wires that the bus operates on. Each sensor can then be addressed individually to perform a range finding cycle or return the range data.

I2CXL-MaxSonar[®]-WR[™] General Operation

After going through the power-up cycle, the I2CXL-MaxSonar-WR sensor(s) will remain in an idle state, listening to I2C bus communications. The sensor will always operate as an I2C slave; it is never a bus master. The sensor will wait for a read or write message from a bus master which contains an address that matches the sensors current address (determined during power-up).

By default, the sensor has a shipped 7-bit address of 0x70 (decimal 112). This translates to an equivalent 8-bit write address of hexadecimal E0 (decimal 224), and 8-bit read address of hexadecimal E1 (decimal 225). An explanation is given in the figure below. The address may be changed to any other 7-bit value, except 0x00 (decimal 0). Therefore, a single I2C bus could support up to 127 simultaneous I2CXL-MaxSonar-WR sensors operating on it, as long as the user configuration allows I2C communications work properly.

The sensor may only be reliably addressed at clock speeds up to 100kHz. However, the bus itself may run faster than this as long as the I2CXL-MaxSonar-WR sensor is not being addressed (tested up to 400kHz).

Sampling faster than 10Hz in certain environments that reflect acoustic noise well could cause the sensor to pick up signals from previous range readings and report false data. However, in certain environments it is possible to take range readings at a significantly faster rate (up to 40Hz depending on the application, see the "Take Range Reading" command page for more details).

The diagram above is an I2C addressing explanation: Each address sent over the I2C bus consists of 7 bits. Because each message over the bus is 8 bits long, the final bit when addressing indicates whether the master wishes to write to or read from the addressed slave. As such, the 7-bit version of the address is effectively the 8-bit version divided by 2 and includes only the first seven bits, whereas the 8-bit read and 8-bit write addresses include the final read/write bit in the address. A final ninth bit is sent back from the slave device to either acknowledge or not acknowledge the request—this bit can be used to determine whether a sensor is responding to the written address.

Reading from the sensor

After an address match with a read request, the sensor will return the high byte, followed by the low byte (to be interpreted as a 16-bit word), of the latest range reading in centimeters, followed by hexadecimal FF (decimal 255) for each subsequent byte requested. If the sensor receives a range request after power up without taking a range reading (i.e. receiving the "Take Range Reading" command), the sensor will respond with two bytes containing information used for in-factory manufacturing purposes. Therefore, a bus master simply needs to request two bytes back from the sensor after a range cycle to determine the range to a target. The diagram below is an I2C command diagram for reading back two bytes from the sensor after taking a range reading. The stop is optional and signifies only that the bus master does not wish to communicate further.

Start	ADDRESS	R	ACK	High byte	ACK	Low byte	NACK	Stop
Bus Master				Sensor	Bus Master	Sensor	Bus Ma	aster

The diagram below shows the SCL and SDA signals for the I2C read request operation. Notice that the sensor will clock stretch after every ACK, while preparing to respond with the latest byte of data. The sensor will release the clock line as soon as the sensor is ready to respond with the latest byte. This clock stretching must be supported if operating over approximately 25kHz clock rate (the clock stretching becomes trivial compared to the time between rising edges).

	SDA A7 A6 A5 A4 A3 A2 A1 R/W ACK D7 D6 D5 D4 D3 D2 D1 D0 ACK D7 D6 D5 D4 D3 D2 D1 ACK D7 D6 D5 D4 D3 D2 D1 D0 NACK								
SCL									
Start	ADDRESS	R	АСК	High byte	АСК	Low byte NACK	Stop		

Bus Master

Sensor

Bus Master

Sensor

Writing to the sensor

Bus Master

Command	Hexadecimal Value	Decimal Value	Explanation
Take Range Reading	51	81	Sensor takes a new range reading
I2C Change Address 1	AA	170	1st command of 2-command sequence to change the I2C address.
I2C Change Address 2	A5	165	2nd command of 2-command sequence to change the I2C address.

After an address match with a write request, all data written to the sensor over the bus is compared to the command set that the I2CXL-MaxSonar-WR series supports; a summary is included above. A match of the received data by the sensor with a command will cause the specific action to be performed. If a value sent to the sensor does not correspond to one of the available commands, no action is taken by the sensor.

I2C Command Description

Take Range Reading

After receiving a byte from a bus master with a value of the ranging command and responding with the ACK, the sensor will stop responding to I2C communications sent to it. Within 50 microseconds of the ACK bit being generated, the sensor will drive pin 2 high. The sensor will transmit the ultrasonic pulse that will be used to measure distance, and proceed to measure the time of flight to a detectable target. After detecting a target and determining the range (from approximately 15 milliseconds up to approximately 60 milliseconds after raising pin 2 high), the sensor will resume I2C communications and return to an idle state while listening for incoming messages. Pin 2 will then be brought low to indicate the sensor is ready to communicate via I2C again.

If the sensor is addressed while in the middle of a range reading, all requests for communication will be responded with a NACK. If the sensor receives a read request while ranging, it will respond with NACK for the initial request, and all data bytes returned will be equal to hexadecimal FF.

The figure below shows the I2C command diagram of how to command the sensor to take a range reading. After addressing the sensor with a write request, the "Take Range Reading" command value (0x51, decimal 81) must be written to the sensor. After acknowledging receipt of the command, the sensor will take a range reading.

Start	Address	w	АСК	Range Command (0x51)	АСК	Stop	
	Bus Master		Sensor	Bus Master	Sensor	Bus Master	

I2C Address Change

Through power cycles, the I2CXL-MaxSonar-WR/WRC sensor stores a permanent address in internal EEPROM, which will be used on power up for I2C communications if Pin 1 (Address Reset) is left disconnected or held high. Users may change the power-up address to suit their application by performing the address change sequence. It is recommended to avoid changing the address often, as it could cause premature EEPROM failure due to repeated erase/write cycles. The sensor includes a safeguard of requiring two separate values to be sent in sequence before changing the stored address. In order to change the address, the two address change commands, 0xAA (decimal 170) and 0xA5 (decimal 165) must be sent to the sensor sequentially in a single message, with no other bytes in between the commands. The next byte received in the same message will become the new address. If there are no bytes sent within the same message on the bus to the sensor needs to have the address changed. The sensor will not accept a new address of 0x00 (decimal 0); if the new address of 00 is sent after receiving the two commands to change the address, the sensor will ignore the new address and continue waiting for a valid new address to be received, unless the bus master stops the transaction with a stop or restart condition. The address must be written in an 8-bit read/write format to the sensor (i.e. one would write 0xE0 to the sensor to set the EEPROM address back to the shipped default).

After receiving a valid byte to change the I2C address to, the sensor will write the new address to internal EEPROM, taking approximately 50 milliseconds. The sensor will then reset itself to go through the power-up cycle again. It is very important that power to the sensor is not disrupted while it is writing to EEPROM, or EEPROM corruption could occur. In the event of severe EEPROM corruption, the sensor will default on power up to using the default shipped address.

Start	Address	w	АСК	I2C Change Address 1 (0xAA)	АСК	I2C Change Address 2 (0xA5)	АСК	New 8-bit I2C Address	ACK	Stop
	Bus Master		Sensor	Bus Master	Sensor	Bus Master	Sensor	Bus Master	Sensor	Bus Master

Above is the I2C command diagram for changing the sensor address. The two I2C "Change Address" commands must be sent sequentially in the same message, with the new valid (non-zero) address following the commands for a change to occur. After receiving the 8-bit address and responding with ACK, the sensor will update internal EEPROM and then reset itself.

Real-time Noise Rejection

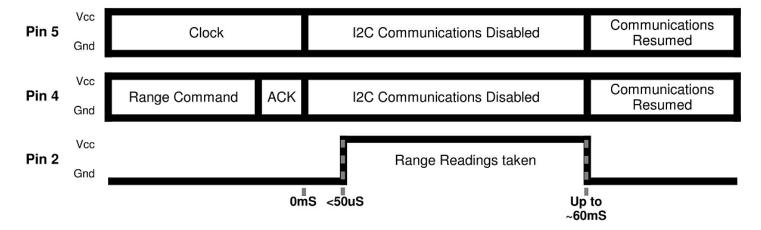

While the I2CXL-MaxSonar-WR/WRC is designed to operate in the presence of noise, best operation is obtained when noise strength is low and desired signal strength is high. The user is encouraged to mount the sensor in such a way that minimizes outside acoustic noise pickup. In addition, keep the DC power to the sensor free of noise. This will let the sensor deal with noise issues outside of the users direct control (in general, the sensor will still function well even if these things are ignored). Users are encouraged to test the sensor in their application to verify usability. For every ranging cycle, individual filtering for that specific cycle is applied. In general, noise from regularly occurring periodic noise sources such as motors, fans, vibration, etc., will not falsely be detected as an object. This holds true even if the periodic noise increases or decreases (such as might occur in engine throttling or an increase/decrease of wind movement over the sensor). Even so, it is possible for sharp non-periodic noise sources to cause false target detection. In addition, (because of dynamic range and signal to noise physics,) as the noise level increases, at first only small targets might be missed, but if noise increases to very high levels, it is likely that even large targets will be missed.

The I2CXL-MaxSonar-WR series has additional resistance against periodic noise and small target rejection capabilities over the standard XL-MaxSonar-WR series.

Real Time Ranging Operation

The diagram depicts the real time operation of the sensor for the SDA and SCL lines, and the status line. Pin 2 is raised from low to high almost immediately after receiving the range command, and will be brought back low as soon as the sensor detects a target, and begins listening to the I2C bus again. The sensor will then be ready to take a new range reading or report the results from the last range reading. The sampling period may take between approximately 15 to 60 milliseconds to detect a target, so it is only possible to achieve higher sampling rates from the sensor if targets are detected up close.

The sensor will always report a range between 20-cm and 765-cm. If a target is detected closer than 20-cm, the sensor will typically report the distance as 20-cm, and if no target is detected by the time a target at 765-cm would have been found, the sensor will limit the maximum reported distance to 765-cm.

Real Time Ranging Operation

I2CXL-MaxSonar[®]-WR[™] Power-up Timing Description

After applying stable, clean power, the sensor will drive Pin 2 (Status) low, and then undergo initialization and setup for approximately 50 milliseconds. During this time, the sensor will be unresponsive to all I2C communications. After the setup has finished, Pin 1 (Add-Reset) will be internally pulled high through a weak pull-up. The state of Add-Reset is checked for approximately 20 milliseconds. If Pin 1 is left high, the sensor will use the address stored in internal EEPROM for I2C communications . If Pin 1 is low, the sensor will use the default shipped address of 0xE0 (decimal 224). In the event that the sensor determines extreme EEPROM corruption has occurred, the sensor will use the default shipped address.

Then, approximately 70 milliseconds after power is applied, Pin 2 will be driven from low to high for a period of 100 microseconds times the value of the address being used (depending on the state of Add-Reset), for up to approximately 25 milliseconds. After approximately 50 more milliseconds, the sensor will be ready to receive I2C commands over the bus.

The formula used for calculating the pulse width length of the I2C address is as follows:

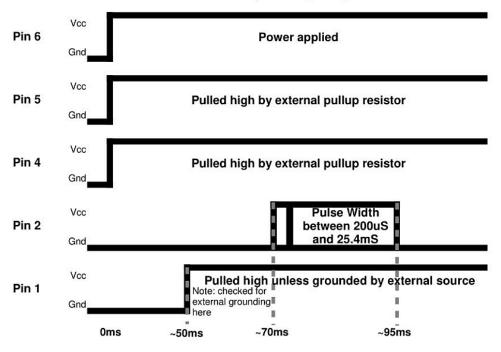

Pulse width length (microseconds) = 100 × value of 8-bit write address, or

Pulse width length (microseconds) = $200 \times$ value of 7-bit address

Therefore, to determine the address the sensor is using after measuring the pulse width length -

Value of 7-bit address = Pulse width length (microseconds) \div 200, or

Value of 8-bit write address = Pulse width length (microseconds) ÷ 100

Power-up Timing Diagram

Target Size Compensation

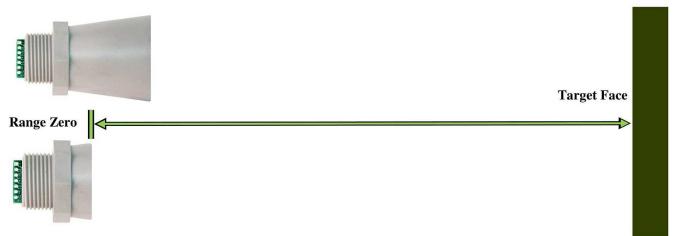

The I2CXL-MaxSonar-WR/WRC sensors do not apply target size compensation to detected objects. This means that larger size targets may report as a closer distance than the actual distance or smaller size targets may report as a further distance then the actual distance.

Real-Time Auto Calibration

Each time before the I2CXL-MaxSonar-WR/WRC sensor takes a range reading, it calibrates itself. The sensor then uses this data to range objects. If the humidity or applied voltage changes during sensor operation, the sensor will continue to function normally. The sensor does not apply compensation for the speed of sound change versus temperature to any range readings.

Range "0" Location

The I2CXL-MaxSonar-WR and I2CXL-MaxSonar-WRC reports the range to distant targets starting from the front of the transducer as shown in the diagram below.

The range is measured from the front of the transducer to the target.

The I2CXL-MaxSonar-WR/WRC will typically report the range to the closest detectable object. Target detection has been characterized in the sensor beam patterns.

I2CXL-MaxSonar[®]-WR[™] Beam Characteristics

Background Information Regarding our Beam Patterns

Each I2CXL-MaxSonar-WR/WRC sensor has a calibrated beam pattern. Each sensor is matched to provide the approximate detection pattern shown in this datasheet. This allows end users to select the part number that matches their given sensing application. Each part number has a consistent field of detection so additional units of the same part number will have similar beam patterns. The beam plots are provided to help identify an estimated detection zone for an application based on the acoustic properties of a target versus the plotted beam patterns.

Each beam pattern is a 2D representation of the detection area of the sensor. The beam pattern is actually shaped like a 3D cone (having the same detection pattern both vertically and horizontally). Detection patterns for dowels are used to show the beam pattern of each sensor. Dowels are long cylindered targets of a given diameter. The dowels provide consistent target detection characteristics for a given size target which allows easy comparison of one MaxSonar sensor to another MaxSonar sensor.

For each part number, the four patterns (A, B, C, and D) represent the detection zone for a given target size. Each beam pattern shown is determined by the sensor's part number and target size.

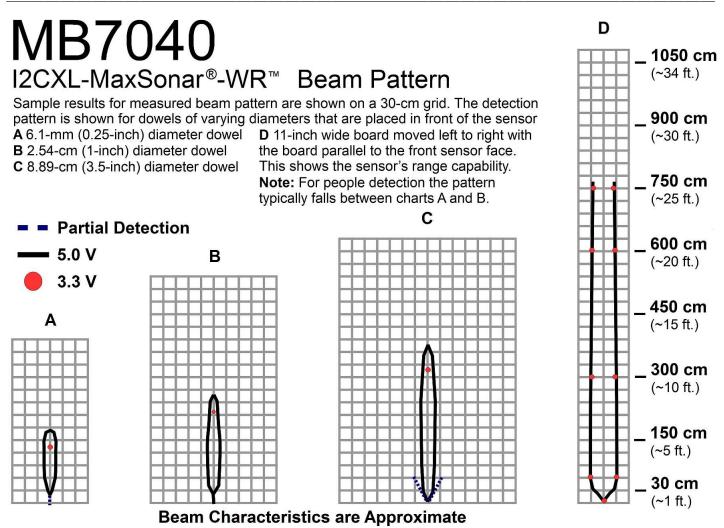

The actual beam angle changes over the full range. Use the beam pattern for a specific target at any given distance to calculate the beam angle for that target at the specific distance. Generally, smaller targets are detected over a narrower beam angle and a shorter distance. Larger targets are detected over a wider beam angle and a longer range.

Compared to the XL-MaxSonar-WR line, the I2CXL-MaxSonar-WR lines offers slightly tighter beam patterns compared to the same model number (i.e. I2CXL-MaxSonar-WR versus XL-MaxSonar-WR1).

People Sensing: For users that desire to detect people, the detection area to the 1-inch diameter dowel, in general, represents the area that the sensor will reliably detect people.

MB7040: I2CXL-MaxSonar[®]-WR[™]

The I2CXL-MaxSonar-WR is the recommended weather-resistant sensor. This sensor is ideal for environments with multiple sensors where the I2C interface simplifies wiring and hook-up. It features a long, narrow beam pattern with high sensitivity.

Beam Patterns drawn to a 1:95 scale for easy comparison to our other products.

MB7040 Features and Benefits

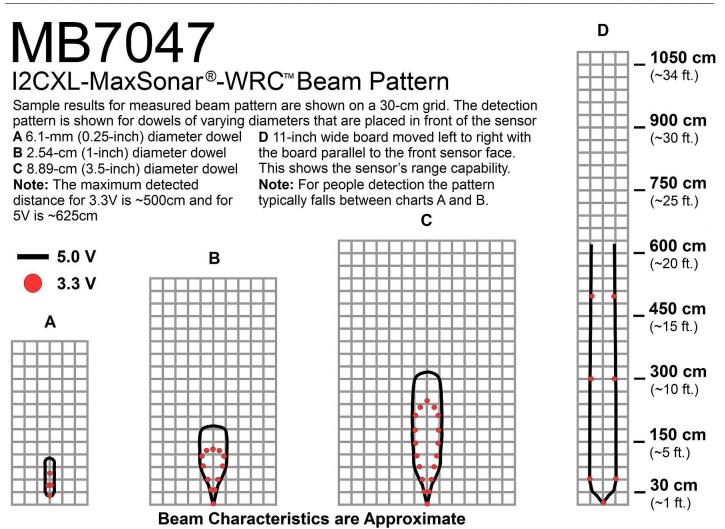

- Low power consumption
- Narrow, controlled beam
- Easy to use interface
- Detects smaller objects
- Can be powered by many different types of power sources

MB7040 Applications and Uses

- People detection
- Security
- Motion detection
- Useable with battery power
- Autonomous navigation
- Educational and hobby robotics
- Collision avoidance

MB7047: I2CXL-MaxSonar[®]-WRC[™]

The I2CXL-MaxSonar-WRC is the compact version of the MB7040. It's ideal for applications where size and weight are restricted and the larger MB7040 is unsuitable. The beam pattern for the MB7047 is slightly wider and shorter than the MB7040.

Beam Patterns drawn to a 1:95 scale for easy comparison to our other products.

MB7047 Features and Benefits

- Low power consumption
- Easy to use interface
- Can be powered by many different types of power sources
- Can detect people up to approximately 6 feet

MB7047 Applications and Uses

- Security
- Motion detection
- Useable with battery power
- Autonomous navigation
- Educational and hobby robotics
- Collision avoidance

Have the right MaxSonar[®] for your application? Check out our MaxSonar[®] Product Lines

Accessories MB7954 - Shielded Cable

The MaxSonar Connection Wire is used to reduce interference caused by electrical noise on the lines. This cable is a great solution to use when running the sensors at a long distance or in an area with a lot of EMI and electrical noise. MaxBotix Inc., has successfully tested our sensors at a distance of 1,000 ft. using this wire and it was as stable as if it were next to the power supply.

MB7950 -XL-MaxSonar-WR Mounting Hardware

The MB7950 Mounting Hardware is selected for use with our outdoor ultrasonic sensors. The MB7950 Mounting Hardware gives customers easy access to the hardware needed for through hole mounting. The mounting hardware includes a steel lock nut and two O-ring (Buna-N and Neoprene) each optimal for different applications.

MB7955 / MB7956 / MB7957 / MB7958 / MB7959- MaxTemp

The HR-MaxTemp is an optional accessory for the HR-MaxSonar. The HR-MaxTemp is a temperature sensor that connects to pin 1 and 7 of the HR-MaxSonar for automatic temperature compensation without self heating or temperature gradient effects.
